

IN THE CLAIMS:

1. (Currently Amended) A railroad hopper car discharge gate assembly, comprising:
a rigid frame configured with a generally ~~rectangular~~ square and ledgeless discharge opening greater than 1600 square inches whereby allowing for rapid discharge of commodity therethrough, with a gate having a an upper surface defining an area generally equivalent to the size of the discharge opening and being mounted on said frame for generally linear movements in a predetermined plane between a closed position, wherein said gate prevents flow of commodity through said discharge opening and, and an open position, and wherein said frame is ~~further~~ configured to inhibit bending of said frame and said ~~door~~ gate under columnar loading adapted to be applied to the greater than 1600 square inches of surface area defined by said gate and which is exposed to commodity carried by a railcar to which said gate assembly is adapted to be operably coupled, with said frame including an upper flange extending outwardly and about a periphery of said frame for facilitating connection of said gate assembly to a hopper of a railroad car, said frame further including wall structure rigidly connected to and depending from said upper flange, and wherein said predetermined plane of movement of said gate is disposed in vertically spaced relation below said upper flange;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when the gate is in the closed position, with said seal structure being carried by said frame in vertically spaced relation below said upper flange and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

In Re Application Of:
R. S. Fortuna
Serial No.: 10/685,608

Page 23

an operating shaft assembly supported by opposed frame extensions for rotation about a fixed axis, with said operating shaft assembly being operably coupled to said gate; and

a lock assembly operable in timed relation relative to rotation of said operating shaft assembly, said lock assembly including a stop which, when said gate is in the closed position, positively engages with the gate thereby preventing inadvertent movement of said gate toward the open position and which is operably removed from the path of movement of the gate prior to said gate being positively moved under the influence of said operating shaft assembly moved toward the open position.

2. (Canceled)

3. (Currently Amended) The railroad hopper car discharge gate assembly according to Claim 1 wherein said frame further includes a plurality of laterally spaced support members arranged in generally parallel relation relative to the direction in which said gate moves between the open and closed positions for limiting deflection of said gate and increasing stiffness of said frame.

4. (Original) The railroad hopper car discharge gate assembly according to Claim 3 wherein each of said support members is provided with material for enhancing the ability of the gate to slide thereover as said gate moves between the closed and open positions.

In Re Application Of:

R. S. Fortuna

Serial No.: 10/685,608

Page 24

5. (Original) The railroad hopper car discharge gate assembly according to Claim 1 wherein said operating shaft assembly is operably coupled to said gate through pinions mounted on a shaft rotatable about said fixed axis, with said pinions being arranged in intermeshing relation with racks carried by said gate.
6. (Original) The railroad hopper car discharge gate assembly according to Claim 5 wherein said frame further includes structure for limiting deflection of the shaft of said operating shaft assembly relative to said fixed axis when said shaft is rotated to move said gate toward the open position.
7. (Original) The railroad hopper car discharge gate assembly according to Claim 1 wherein the stop of said lock assembly is urged into releasable engagement with said gate.
8. (Original) The railroad hopper car discharge gate assembly according to Claim 1 wherein a mechanical system is provided between the stop of said lock assembly and said operating shaft assembly for positively displacing said stop from engagement with said gate upon rotation of said operating shaft assembly and prior to movement of said gate toward the open position.
9. (Original) The railroad hopper car discharge gate assembly according to Claim 8

In Re Application Of:

R. S. Fortuna

Serial No.: 10/685,608

Page 25

further including a lost motion mechanism which collapses upon rotation of the operating shaft assembly in a direction to move the gate toward the open position whereafter said operating shaft assembly is operably coupled to said gate.

10. (Currently Amended) A railroad hopper car discharge gate assembly, comprising:

a frame including a pair of spaced, generally parallel side frame members and a pair of spaced, generally parallel end frame members fixed between said side frame members to define a ledgeless discharge outlet for said gate assembly;

a gate adapted for sliding endwise movements along a predetermined path of travel between closed and open positions, with said gate including upper and lower generally parallel surfaces;

and wherein, in an area surrounding peripheral edges of said gate, said side frame members and said end frame members each have a first leg portion having wall structure and a second apertured leg first flange portion joined to and extending in generally normal relation away from said first leg portion an upper end of said wall structure, with the spacing between the first leg portions wall structures of said side frame members and said end frame members being generally equal such that the ledgeless discharge outlet for said gate assembly has a generally square configuration and ranges in size between about 1400 and about 1760 square inches, with said frame further including laterally spaced support members disposed generally parallel to said side frame members and between said end frame members in sliding engagement with the lower

Page 26

surface of and for supporting the gate in the closed position against columnar load adapted to be exerted against the upper surface of said gate, with the predetermined path of travel of said gate being disposed in vertically spaced relation below the upper flange on said side frame members and said end frame members, and wherein said side frame members, said end frame members, and said support members are configured to withstand columnar loading adapted to be applied the upper surface of said gate, corresponding in cross-sectional size to the cross-sectional area of said generally square discharge opening, and wherein said side frame members extend away from the discharge outlet for said gate assembly and are configured to support said gate when said gate is moved to an open position;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when the gate is in the closed position, with said seal structure being carried by said frame in vertically spaced relation below the flange on said side frame members and said end frame members and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

an operating shaft assembly carried by said side frame members for rotational movement about a fixed axis, said operating shaft assembly being operably coupled to said gate; and

a lock assembly including a displaceable stop operable in timed relation relative to rotation of said operating shaft assembly for preventing inadvertent movement of said gate toward the open position and which is operably removed from the path of movement of the gate prior to said gate being positively moved under the influence of said operating shaft assembly moved toward

Page 27

the open position.

11. Canceled.

12. (Original) The railroad hopper car discharge gate assembly according to Claim 10 wherein said support members include a first support member extending generally along a longitudinal centerline of said gate assembly along with second and third support members disposed to opposite lateral sides of the longitudinal centerline of said gate assembly.

13. (Original) The railroad hopper car discharge gate assembly according to Claim 12 wherein each support member is provided with material for enhancing the ability of the gate to slide thereover as said gate moves between the closed and open positions.

14. (Original) The railroad hopper car discharge gate assembly according to Claim 10 wherein said operating shaft assembly is operably coupled to said gate through pinions mounted on a shaft rotatable about said fixed axis, with said pinions being arranged in intermeshing relation with racks mounted on the lower surface of said gate.

15. (Original) The railroad hopper car discharge gate assembly according to Claim 14 wherein said operating shaft extends transversely across the predetermined path of travel of said

In Re Application Of:

Serial No.: 10/685,608

Page 28

gate and includes capstans arranged at opposite ends thereof, said capstans being disposed for engagement from either side of said gate assembly.

16. (Original) The railroad hopper car discharge gate assembly according to Claim 15 wherein said frame further includes structure arranged along the length of said operating shaft for minimizing the effect high torque requirements inputted to said operating shaft assembly have on operation of said gate assembly.

17. (Original) The railroad hopper car discharge gate assembly according to Claim 10 wherein said lock assembly further includes a mechanical system carried by said side frame members for positively displacing said stop in timed relation relative to operation of said operating shaft assembly.

18. (Original) The railroad hopper car discharge gate assembly according to Claim 17 wherein said mechanical system includes cam structure disposed adjacent to the side frame members to minimize the effect high torque requirements inputted to said operating shaft assembly have on operation of said lock assembly.

19. (Currently Amended) The railroad hopper car discharge gate assembly according to Claim 18 wherein each side frame member and said end frame member further includes a ~~third leg~~

R. S. Fortuna
Serial No.: 10/685,608

Page 29

second flange portion joined to and extending in generally normal relation away from ~~said first leg portion~~ a lower end of said wall structure, with said ~~third leg~~ second flange portion being spaced from but extending in the same direction as and in generally parallel relation with said ~~second leg~~ first flange portion to add strength and rigidity to said frame.

20. (Currently Amended) The railroad hopper car discharge gate assembly according to Claim 19 wherein a peripheral edge of said cam structure on said operating shaft assembly traverses a path of rotation confined within the spacing provided between said first and second ~~and third leg~~ flange portions of each side frame member.

21. (Currently Amended) The railroad hopper car discharge gate assembly according to Claim 19 wherein a distance of about 9.0 inches is measurable between the said first and second ~~and third leg~~ flange portions of each side frame member and each end frame member.

22. (Currently Amended) The railroad hopper car discharge gate assembly according to Claim 19 wherein the ~~third leg~~ second flange portion on each of the side frame and end frame members of said frame are arranged generally coplanar relative to each other.

23. (Original) The railroad hopper car discharge gate assembly according to Claim 17 further including a lost motion mechanism operably disposed between said operating shaft

In Re Application Of:

Serial No.: 10/685,608

Page 30

assembly and the mechanical system for said lock assembly for effecting sequential movement of the stop and said gate in predetermined relation relative to each other.

24. (Original) The railroad hopper car discharge gate assembly according to Claim 23 wherein said stop is mounted on and movable with a rockshaft extending parallel to and above said gate, said rockshaft having at least one follower toward one end thereof for engaging a periphery of a cam arranged toward a corresponding end of said operating shaft assembly thereby positively moving said stop regardless of the torque input to said operating shaft assembly.

25. (Original) The railroad hopper car discharge gate assembly according to Claim 10 wherein a tamper seal arrangement is arranged in combination with said operating shaft assembly for accepting a seal for visually indicating whether said gate has been moved toward the open position.

26. (Currently Amended) A gate assembly adapted to be secured in material receiving relation relative to a standard opening defined toward a bottom of a railroad hopper car, said gate assembly comprising:

a rigid frame having a longitudinal axis and including a series of rigidly interconnected side frame members and end frame members which are spaced relative to each other and configured to provide said frame with a ledgeless and generally ~~rectangular~~ square discharge opening sized

In Re Application Of:
R. S. Fortuna
Serial No.: 10/685,608

Page 31

substantially equivalent to the standard opening defined toward the bottom of the railroad hopper car whereby allowing commodity discharged from the opening in the bottom of the railcar to pass through said gate assembly in a substantially unhindered fashion thereby promoting the discharge of commodity from the railcar, with said side frame members and said end frame members defining a bolting pattern generally corresponding to a standard bolting pattern surrounding the standard opening toward the bottom of the railroad hopper car whereby facilitating securement of the gate assembly to the railroad hopper car, with each side frame member and end frame member including a peripheral flange portion joined to and extending outward from an upper end of depending wall structure, and wherein said ledgeless frame further includes a generally centralized support extending generally parallel to the longitudinal axis of said frame with two additional supports disposed to opposed sides of said centralized support;

a gate slidably mounted on said frame for endwise movements between open and closed positions relative to said ledgeless opening defined by said frame and along a generally linear path of movement for controlling discharge of commodity through said ledgeless opening, with said gate being supported by said supports when in the closed position and supported by said frame when moved to the open position, and wherein the linear path of movement of said gate is disposed vertically beneath the flange portion on each side frame member and end frame member of said rigid frame;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when said gate is in the closed position, with said seal structure being

In Re Application Of:

R. S. Fortuna

Page 32

carried by said frame in vertically spaced relation below the flange on said side frame members and said end frame members and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

an operating shaft assembly mounted on frame extension of said side frame members for rotation about a fixed axis, said operating shaft assembly defining a pair of opposed ends disposed for operator access from opposite sides of said frame;

a drive mechanism for operably coupling said operating shaft assembly to the gate whereby rotation of said operating shaft assembly linearly moves said gate between the open and closed positions, with said drive mechanism including a lost motion mechanism operably disposed between said operating shaft assembly and said gate for allowing a predetermined range of free rotation of said operating shaft assembly prior to movement of said gate toward the open position; and

a lock assembly operably connected to said operating shaft and operable in timed relation relative to movement of said gate toward the open position, said lock assembly including a stop mounted for movement between a first position, wherein said stop is disposed in the path of movement of said gate whereby inhibiting inadvertent movement of the gate from the closed position toward the open position, and a second position, wherein said stop is removed from the path of movement of the gate, with said stop being movable from said first position to said second position during the collapse of the lost motion mechanism of said drive mechanism.

In Re Application Of:
R. S. Fortuna
Serial No.: 10/685,608

Page 33

27. (Original) The gate assembly according to Claim 26 wherein each support on said frame is provided with material for enhancing the ability of the gate to slide thereover as said gate moves between the closed and open positions.

28. Canceled.

29. (Original) The gate assembly according to Claim 26 wherein said drive mechanism includes a pair of laterally spaced pinions mounted on a shaft of said operating shaft assembly, with said pinions being arranged in intermeshing relation with racks carried by said gate.

30. (Original) The gate assembly according to Claim 29 wherein said lost motion mechanism of said drive mechanism comprises a slip socket defined by each of said laterally spaced pinions.

31. (Original) The gate assembly according to Claim 26 wherein said frame further includes structure for limiting deflection of said shaft of said shaft assembly relative to said fixed axis when said operating shaft assembly is rotated to move said gate from the closed to the open position.

32. (Currently Amended) The gate assembly according to Claim 26 wherein said lock

Page 36

visually indicating whether said gate has been moved toward the open position.

Please add new Claims 40 through 63 as follows:

40. (New) A railroad hopper car discharge gate assembly, comprising:

a rigid frame configured with a generally square and ledgeless discharge opening greater than 1600 square inches whereby allowing for rapid discharge of commodity therethrough, with a gate having an upper surface defining an area generally equivalent to the size of the discharge opening and being mounted on said frame for generally linear movements in a predetermined plane between a closed position, wherein said gate prevents flow of commodity through said discharge opening and, and an open position, and wherein said frame is configured to inhibit bending of said frame and said gate under columnar loading adapted to be applied to the greater than 1600 square inches of surface area defined by said gate and which is exposed to commodity carried by a railcar to which said gate assembly is adapted to be operably coupled, with said frame including an upper flange extending outwardly and about a periphery of said frame for facilitating connection of said gate assembly to a hopper of a railroad car, said frame further including wall structure rigidly connected to and depending from said upper flange, and wherein said predetermined plane of movement of said gate is disposed in vertically spaced relation below said upper flange;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when the gate is in the closed position, with said seal structure being carried

In Re Application Of:
R. S. Fortuna
Serial No.: 10/685,608

Page 37

by said frame in vertically spaced relation below said upper flange and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

an operating shaft assembly supported on said frame for rotation about a fixed axis, with said operating shaft assembly being operably coupled to said gate; and

a lock for inhibiting inadvertent movement of said gate from the closed position toward the open position.

41. (New) The railroad hopper car discharge gate assembly according to Claim 40 further including a plurality of laterally spaced support members carried by said frame and arranged in generally parallel relation relative to the direction in which said gate moves between the open and closed positions for limiting deflection of said gate.

42. (New) The railroad hopper car discharge gate assembly according to Claim 40 wherein said operating shaft assembly is operably coupled to said gate through pinions mounted on a shaft rotatable about said fixed axis, with said pinions being arranged in intermeshing relation with racks carried by said gate.

43. (New) The railroad hopper car discharge gate assembly according to Claim 40 wherein the stop of said lock assembly is urged into releasable engagement with said gate.

In Re Application Of:

R. S. Fortuna

Serial No.: 10/685,608

Page 38

44. (New) A railroad hopper car discharge gate assembly, comprising:

a frame including a pair of spaced, generally parallel side frame members and a pair of spaced, generally parallel end frame members fixed between said side frame members to define a ledgeless discharge outlet for said gate assembly;

a gate adapted for sliding endwise movements along a predetermined path of travel between closed and open positions, with said gate including upper and lower generally parallel surfaces;

and wherein said side frame members and said end frame members each have wall structure with a first flange portion joined to and extending in generally normal relation away from an upper end of said wall structure, with the spacing between the wall structures of said side frame members and said end frame members being generally equal such that the ledgeless discharge outlet for said gate assembly has a generally square configuration and ranges in operative size between about 1400 and about 1870 square inches, with laterally spaced support members carried by said frame and extending across said discharge outlet such that said support members extend generally parallel to said side frame members and between said end frame members in sliding engagement with the lower surface of and for supporting the gate in the closed position against columnar load adapted to be exerted against the upper surface of said gate, with the predetermined path of travel of said gate being disposed in vertically spaced relation below the upper flange on said side frame members and said end frame members, and wherein said side frame members, said end frame members, and said support members are configured to withstand

columnar loading adapted to be applied the upper surface of said gate, generally corresponding in cross-sectional size to the cross-sectional area of said generally square discharge opening, and wherein said side frame members extend away from the discharge outlet for said gate assembly and are configured to support said gate when said gate is moved to an open position;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when the gate is in the closed position, with said seal structure being carried by said frame in vertically spaced relation below the flange on said side frame members and said end frame members and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

an operating shaft assembly carried by said side frame members for rotational movement about a fixed axis, said operating shaft assembly being operably coupled to said gate; and

a lock for inhibiting inadvertent movement of said gate from the closed position toward the open position.

45. (New) The railroad hopper car discharge gate assembly according to Claim 44 wherein said support members include a first support member extending generally along a longitudinal centerline of said gate assembly, with second and third support members disposed to opposite lateral sides of the longitudinal centerline of said gate assembly.

46. (New) The railroad hopper car discharge gate assembly according to Claim 45 wherein

In Re Application Of:
R. S. Fortuna
Serial No.: 10/685,608

Page 40

each support member is configured to enhance the ability of the gate to slide thereover as said gate moves between the closed and open positions.

47. (New) The railroad hopper car discharge gate assembly according to Claim 45 wherein said operating shaft assembly is operably coupled to said gate through pinions mounted on a shaft rotatable about said fixed axis, with said pinions being arranged in intermeshing relation with racks mounted on the lower surface of said gate.

48. (New) The railroad hopper car discharge gate assembly according to Claim 47 wherein said operating shaft extends transversely across the predetermined path of travel of said gate and includes capstans arranged at opposite ends thereof, said capstans being disposed for engagement from either side of said gate assembly.

49. (New) The railroad hopper car discharge gate assembly according to Claim 44 wherein said lock assembly further includes a mechanical system carried by said side frame members for positively displacing said stop in timed relation relative to operation of said operating shaft assembly.

50. (New) The railroad hopper car discharge gate assembly according to Claim 49 further including a lost motion mechanism operably disposed between said operating shaft assembly and

In Re Application Of:
R. S. Fortuna

Page 41

the mechanical system for said lock assembly for effecting sequential movement of the stop and said gate in predetermined relation relative to each other.

51. (New) The railroad hopper car discharge gate assembly according to Claim 49 wherein said mechanical system includes cam structure disposed adjacent to the side frame members to minimize the effect high torque requirements inputted to said operating shaft assembly have on operation of said lock assembly.

52. (New) The railroad hopper car discharge gate assembly according to Claim 44 wherein each side frame member and each end frame member of said frame further includes a second flange portion joined to and extending in generally normal relation away from a lower end of said wall structure, with said second flange portion extending in the same direction as and in generally parallel relation with said first flange portion to add strength and rigidity to said frame.

53. (New) The railroad hopper car discharge gate assembly according to Claim 52 wherein a distance of about 9.0 inches is measurable between the said first and second flange portions of each side frame member and each end frame member.

54. (New) The railroad hopper car discharge gate assembly according to Claim 52 wherein the second flange portion on each of the side frame and end frame members of said frame are

peripheral flange portion joined to and extending outward from an upper end of depending wall structure, and wherein said ledgeless frame further includes a generally centralized support extending generally parallel to the longitudinal axis of said frame with two additional supports disposed to opposed sides of said centralized support;

a gate slidably mounted on said frame for endwise movements between open and closed positions relative to said ledgeless opening defined by said frame and along a generally linear path of movement for controlling discharge of commodity through said ledgeless opening, with said gate being supported by said supports when in the closed position and supported by said frame when moved to the open position, and wherein the linear path of movement of said gate is disposed vertically beneath the flange portion on each side frame member and end frame member of said rigid frame;

seal structure arranged in sealing engagement with the upper surface and toward a periphery of said gate when said gate is in the closed position, with said seal structure being carried by said frame in vertically spaced relation below the flange on said side frame members and said end frame members and configured to promote movement of said commodity therepast when said gate is moved toward said open position;

an operating shaft assembly mounted on frame extensions of said side frame members for rotation about a fixed axis, said operating shaft assembly defining a pair of opposed ends disposed for operator access from opposite sides of said frame;

a drive mechanism for operably coupling said operating shaft assembly to the gate

In Re Application Of:
R. S. Fortuna
